

# The CDF Silicon Vertex Trigger

Bill Ashmanskas  
Argonne National Laboratory  
(for the CDF-II Collaboration)  
May 30, 2003

## Outline

- CDF trigger overview → focus on SVT
- How SVT works (performance)
- Why SVT works (diagnostics/flexibility)

# CDF Detector

- CDF: multi-purpose experiment, broad physics program
- Tevatron:  $E_{\text{CM}} = 1.96 \text{ TeV}$ ,  $T_{\text{bunch}} = 396 \text{ (132) ns}$ ,  $L \sim 10^{32} \text{ cm}^{-2} \text{ s}^{-1}$

# CDF trigger (detector) signatures

Trigger exploits a wide variety of signatures ...

- $e, \mu$  from  $W, Z, \text{SUSY}, b$
- $\gamma, \text{jet}, \nu$  (E imbalance),  $\tau, b \text{ jet}, \dots$
- "Displaced" hadrons from bottom and charm decay

... to distinguish processes with a wide range of rates

- $\sim 50 \text{ mb}$  total inelastic
- $\sim 100 \mu\text{b}$  bottom, charm
- $\sim 10 \mu\text{b}$   $B, p_T > 6 \text{ GeV}, |y| < 1$
- $\sim 2 \text{ nb}$   $W \rightarrow e\nu$
- $\sim 5 \text{ pb}$  top

Many trigger signatures use drift chamber tracks, e.g. coincidence of D.C. track with EM cal, muon stub, silicon hits

# Level 1 drift chamber trigger (XFT)

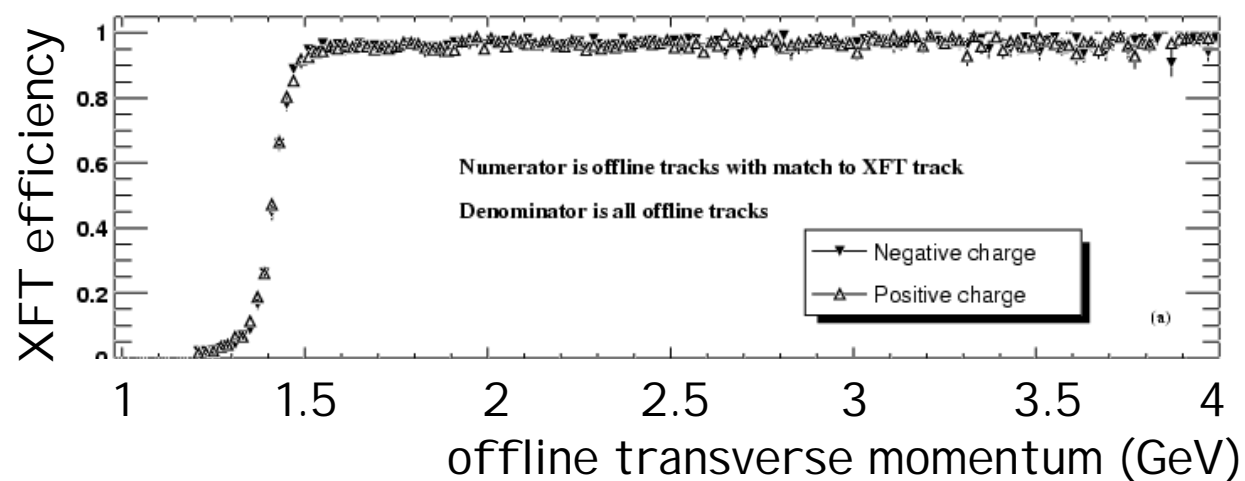

Finds  $p_T > 1.5$  GeV  
tracks in  $1.9 \mu\text{s}$

For every bunch  
crossing (132 ns)!

$$\sigma(1/p_T) = 1.7\%/ \text{GeV}$$

$$\sigma(\phi_0) = 5 \text{ mrad}$$

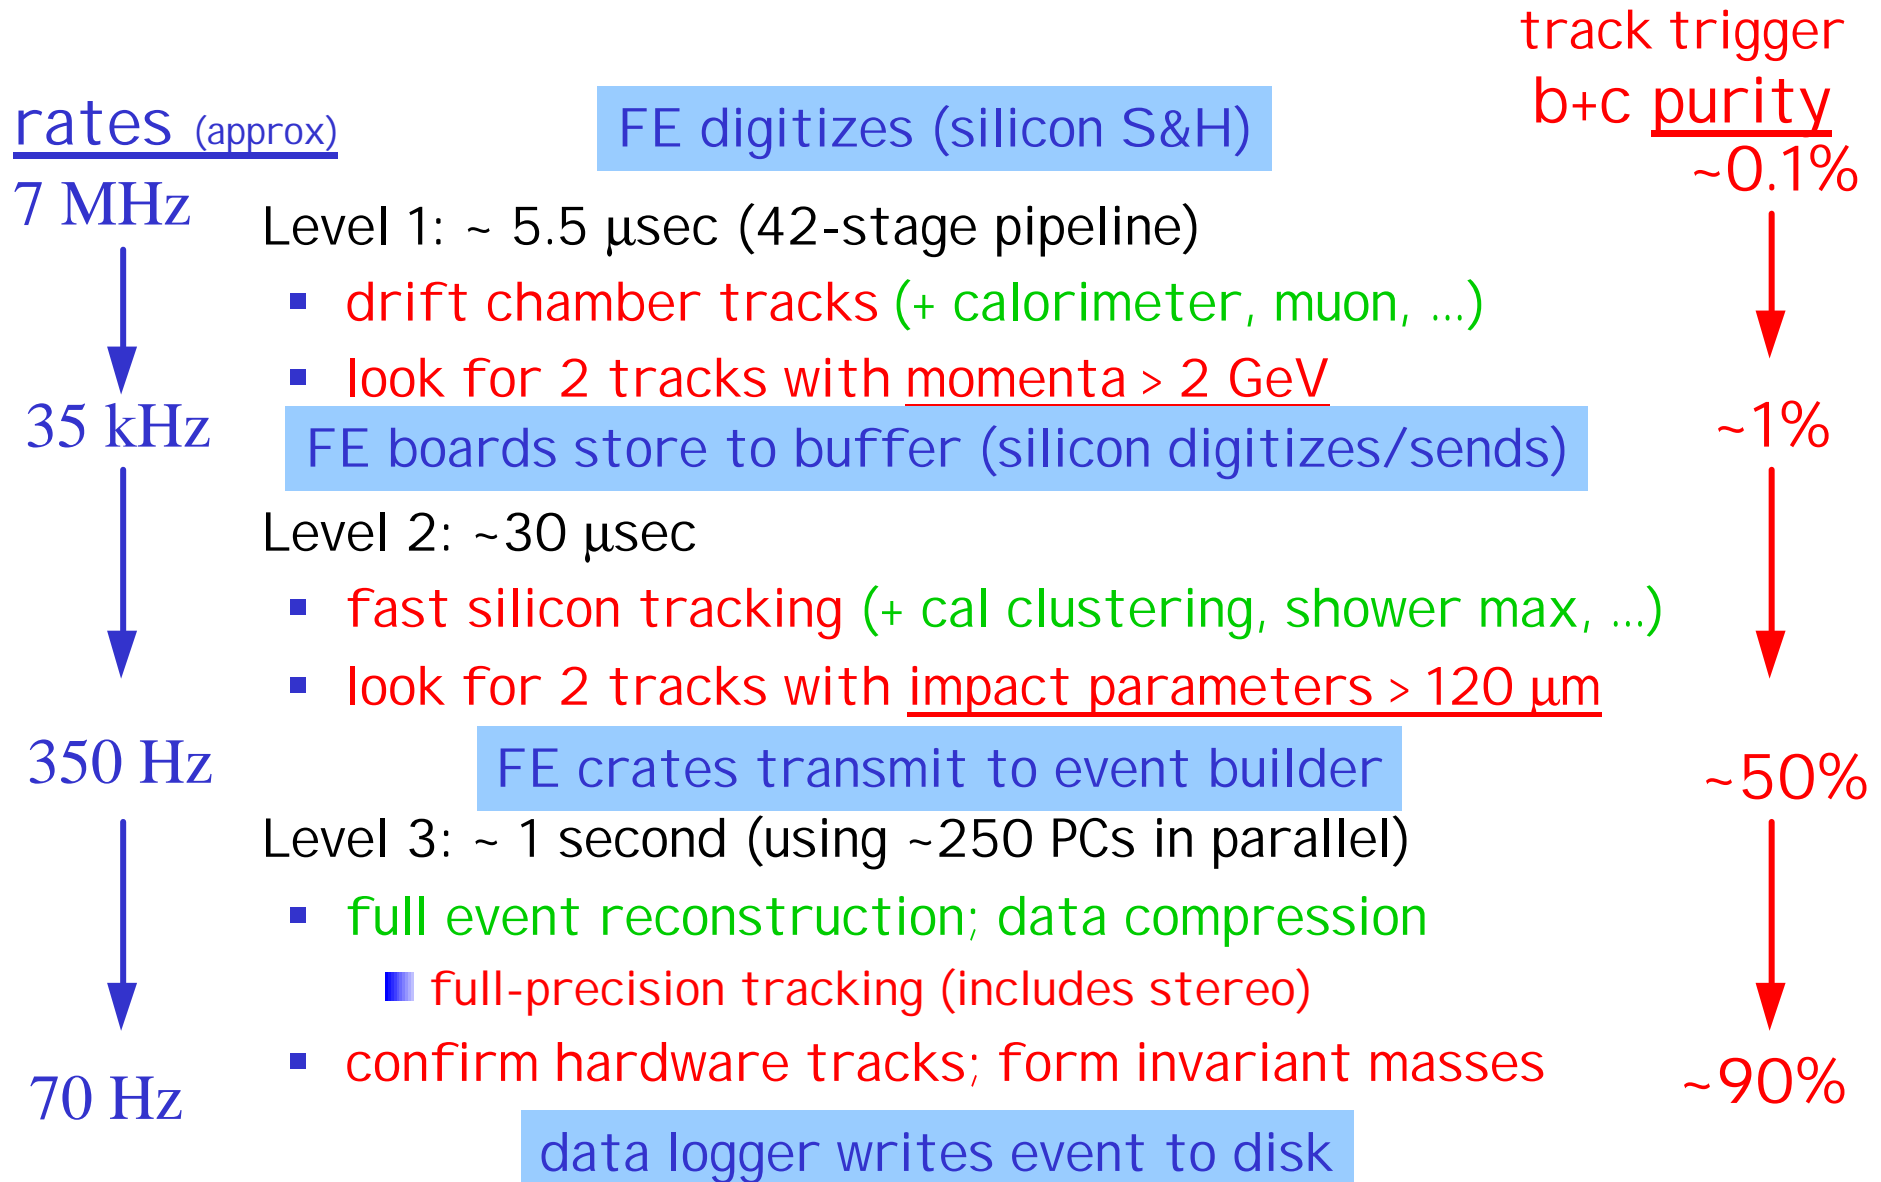

96% efficiency

# Exploit lifetime to select b,c decays

# CDF three-level trigger

# New triggers → a paper from first 12pb<sup>-1</sup>

## CDF approves first Run II paper

by Kurt Riesselmann

Scientists at CDF have announced that they will soon release the first publication based on data obtained from Fermilab's Collider Run II. An internal CDF seminar scheduled for March 7 is likely to be the last step of an elaborate, six-month review process. Barring any objections from members of the CDF collaboration, scientists will publish a mass measurement of particles containing charm quarks in the journal *Physical Review D*.

"It's not a major discovery," said CDF scientist Christoph Paus, professor at MIT. "It's bread-and-butter physics. Over the years, the mass difference between the  $D^+$  and  $D_s^+$  particles has been measured world average. Even more important, the paper is a first."

This is not to say that the CDF scientists or their colleagues at the DZero experiment had ever disappeared. Over the years, the collaborations have published hundreds of papers. The first of a flood of publications expected from Run II is now under way.

It often takes many months or even years before a result is ready to publish results of a specific analysis. In the case of the CDF, it takes almost as much time to convince other members of the collaboration that an analysis was done right and that its conclusions are correct.

"Our results are approved."

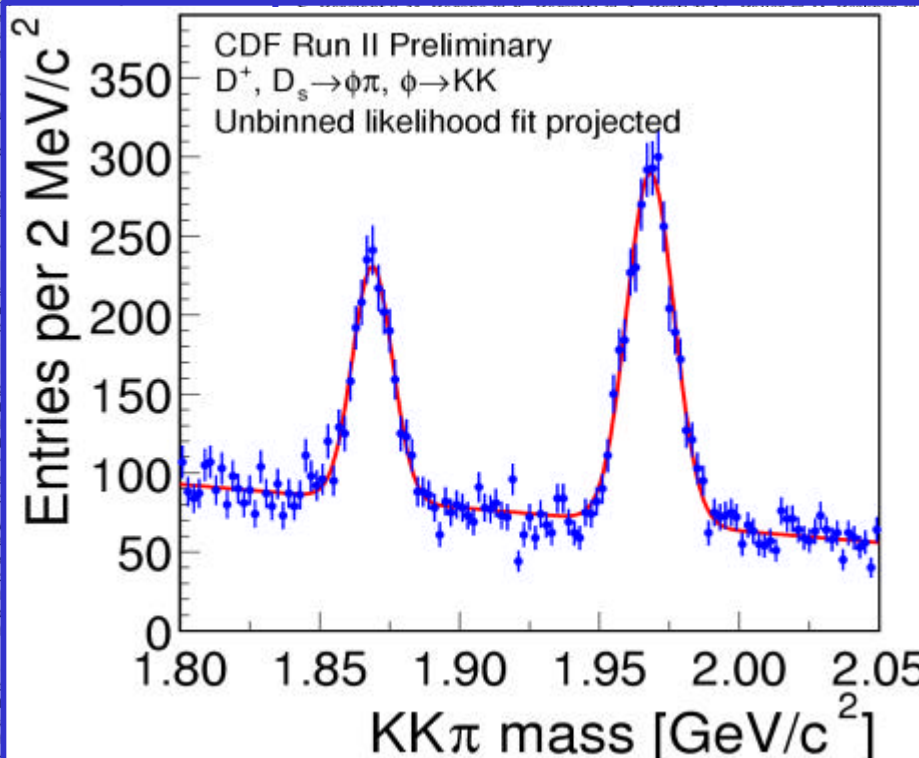

Graduate student Ivan Furic (left) and assistant professor Christoph Paus, both CDF scientists from MIT, carried out the analysis for the first publication of Run II results.

❖ Results:  $M(D_s) - M(D^+) = 99.41 \pm 0.38 \pm 0.21 \text{ MeV}/c^2$

- $99.41 \pm 0.38 \pm 0.21 \text{ MeV}/c^2$
- PDG:  $99.2 \pm 0.5 \text{ MeV}/c^2$

## Position measurement ("hit") for charged particle

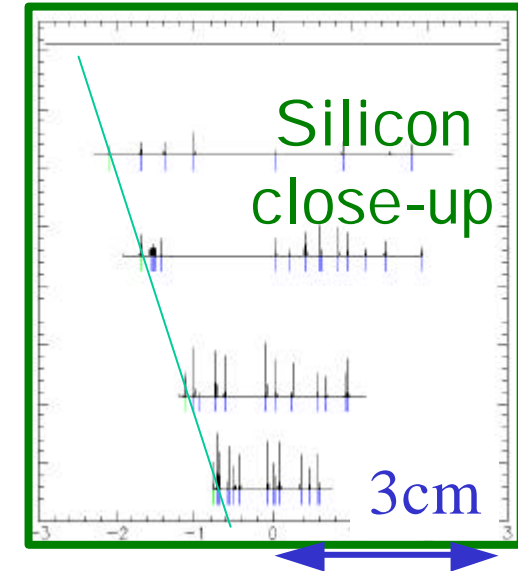

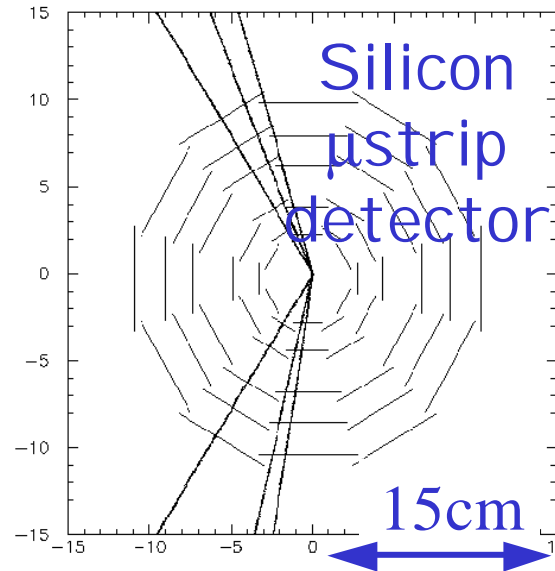

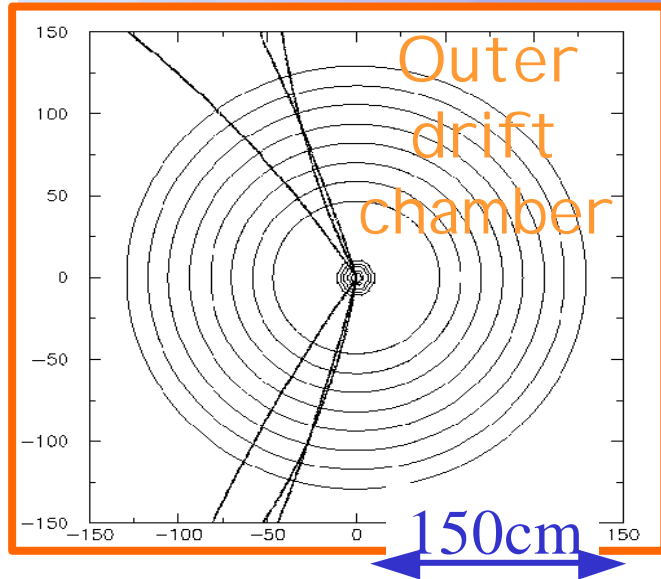

"hit" = charge centroid

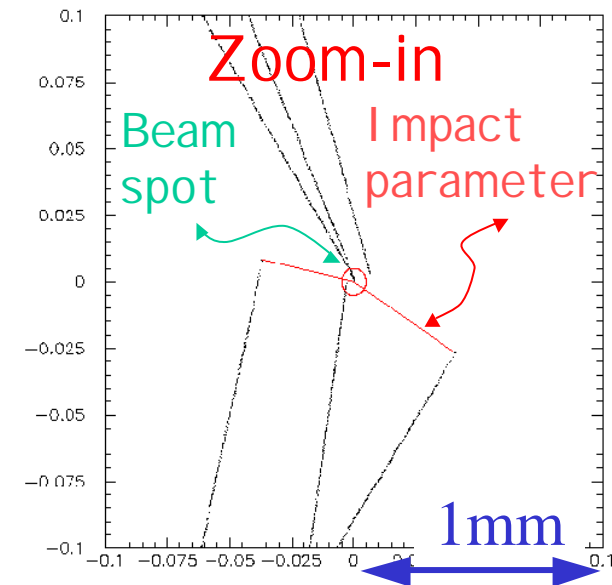

# Silicon trigger problem synopsis

Input (every Level 1 accept):  
outer drift chamber trajectories  
silicon pulse height for each channel

Output (about 20 microseconds later):  
trajectories that use silicon points  
impact parameter:  $\sigma(d)=35\mu\text{m}$

# Doing silicon tracking quickly

Three key features of SVT allow us to do in tens of microseconds what typically takes software hundreds of milliseconds:

- Parallel/pipelined architecture
- Custom VLSI pattern recognition
- Linear track fit in fast FPGAs

# Trick #1: symmetry allows parallelism

Note "wedge" symmetry

Symmetric, modular geometry of silicon vertex detector lends itself to parallel processing

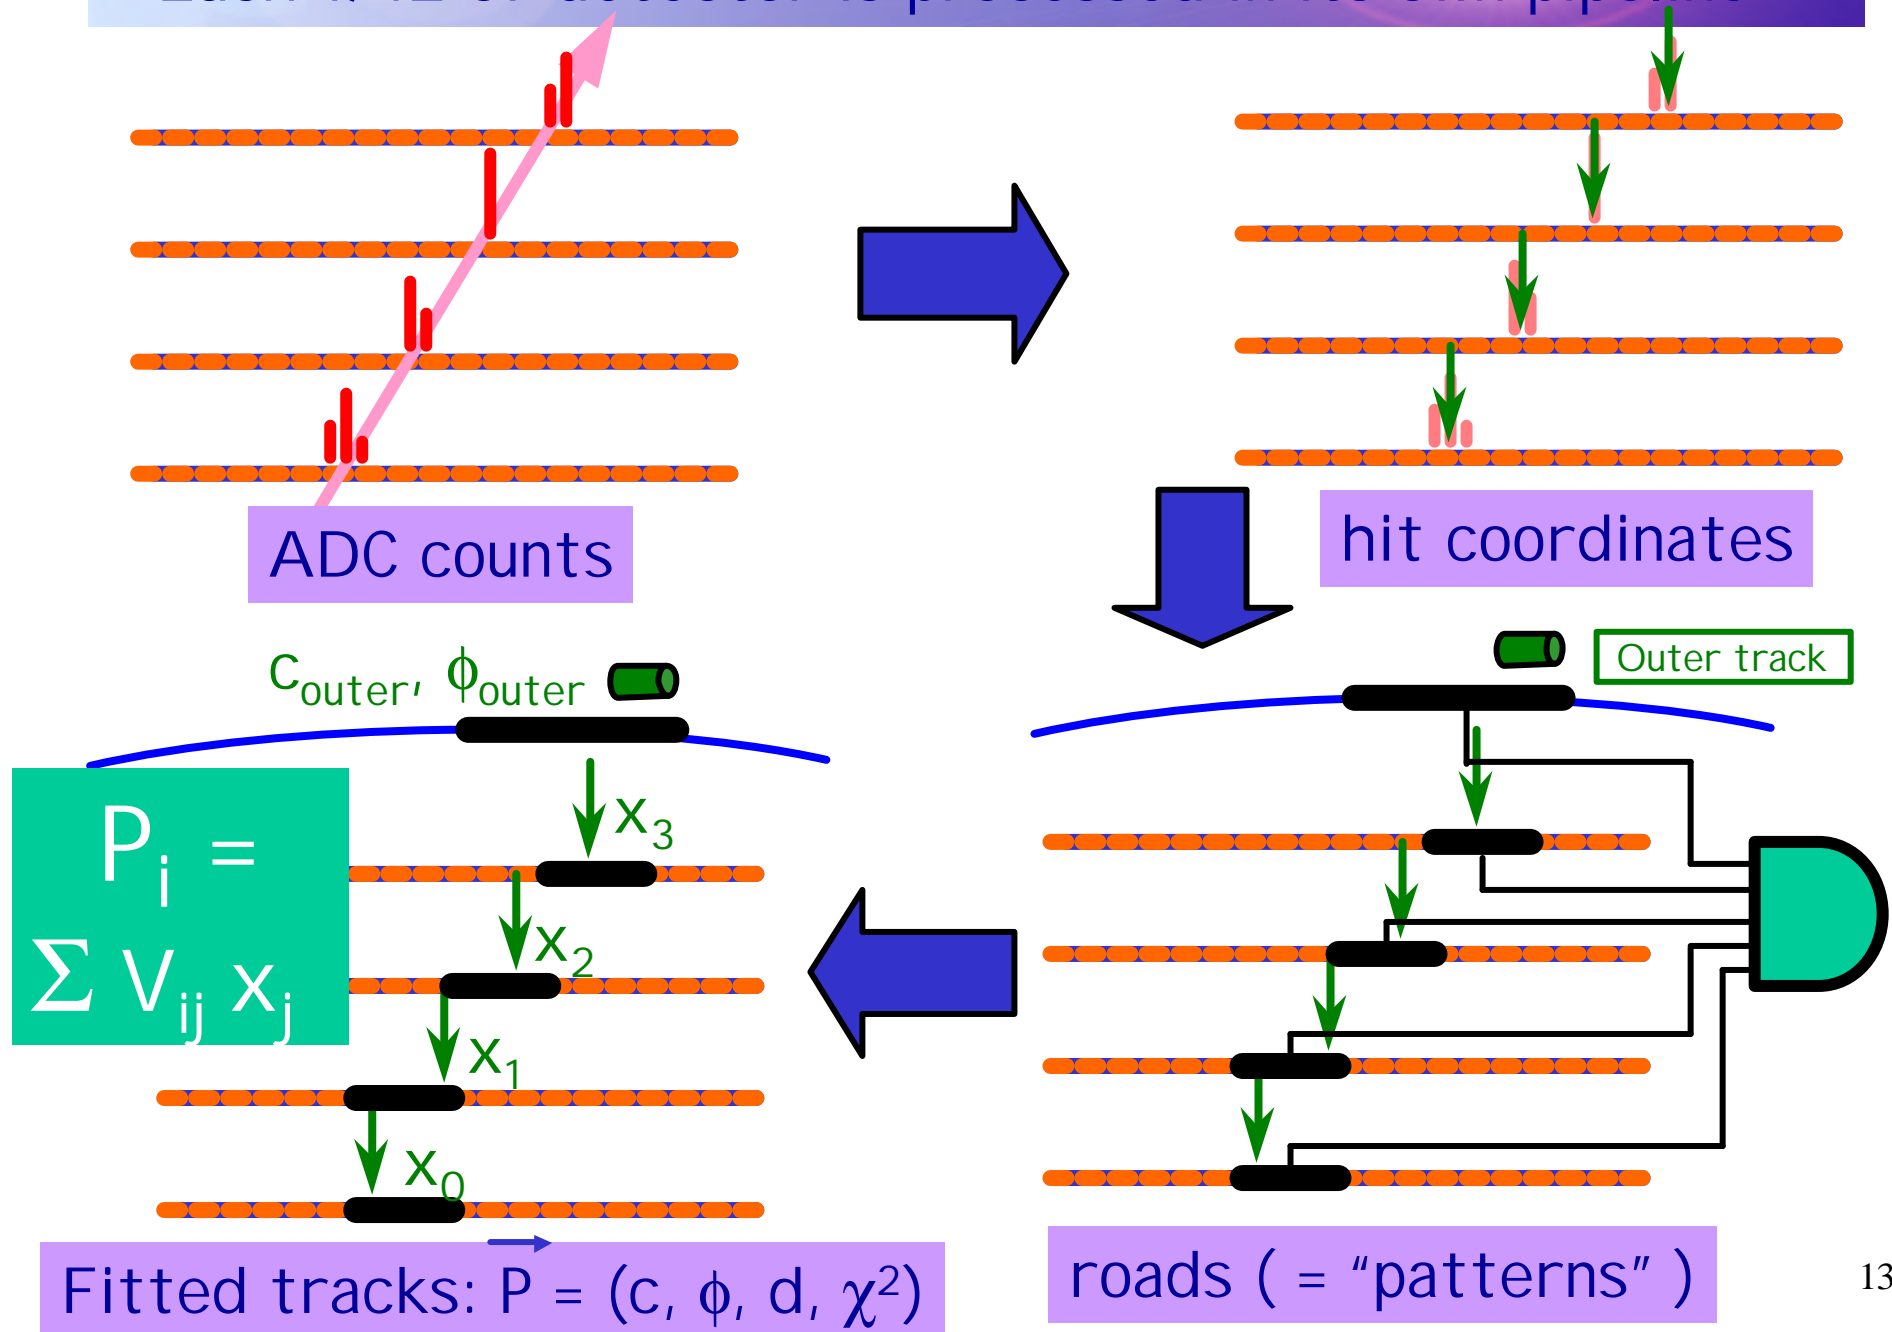

# SVT data volume requires parallelism

Reduces gigabytes/second to megabytes/second

Peak (avg): 20 (0.5) GB/s  $\longrightarrow$  100 (1.5) MB/s

Each 1/12 of detector is processed in its own pipeline

## 2nd trick: streamlined track finding

The way we find tracks is a cross between

- searching predefined roads
- playing BI NGO

$$\text{Time} \sim A * N_{\text{hits}} + B * N_{\text{matched roads}}$$

B	I	N	G	O
2	17	35	48	61
10	21	39	53	66
14	20	free	55	65
8	25	41	52	62
6	16	37	46	67

# Custom VLSI AMchip (pattern recognition)

VME

AMbus

## Trick #3: linear fit

Circle( $\vec{P}$ )  $\subset$  Planes at points  $\vec{x}$   
 $\vec{x}$  not in general linear in  $\vec{P}$

But for  $P > 2$  GeV,  $d < 1$  mm,  
 linear fit biases  $d \sim \text{few } \%$   
 $\Rightarrow$  no problem for trigger

We derive  $V_{ij}$  by linear regression to Monte Carlo data

Trick #3a: use road as a hint  
 precompute  $V_{ij} X_j^{\text{road}}$   
 $\Rightarrow 250$  nsec per fit !

# Least squares fit is performed in FPGA

The 6 scalar products are  
computed in parallel

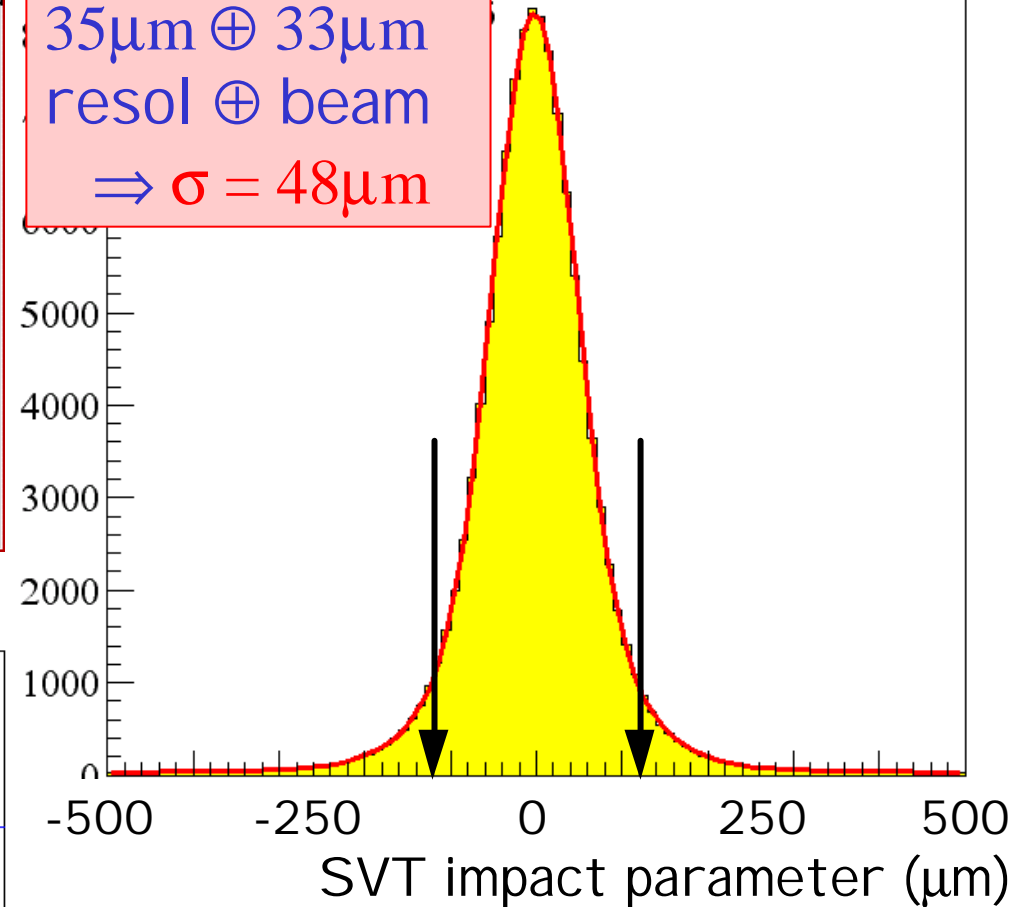

Each fit done in 250nsec

# Performance

$35\mu\text{m} \oplus 33\mu\text{m}$   
resol  $\oplus$  beam  
 $\Rightarrow \sigma = 48\mu\text{m}$

N.B.: lots of trigger & detector work to keep efficiency high  
 $\rightarrow$  Lester Miller's talk on CDF silicon

## Merger & cable capture essence of SVT architecture

- ❖ Universal cable/format for all SVT data (hits, roads, tracks, ...)
- ❖ Mergers fan in/out like NIM logic components
- ❖ Data fan-in done inside FPGAs, not on backplanes
- ❖ Easy to insert a processing stage, switch source on/off, split off a duplicate copy

The board to move the data around was prototyped and tested before other boards were built

SVT Merger Board

Universal cable -> can adapt quickly, as with NI M logic

Most of SVT's cabling was carefully planned a priori

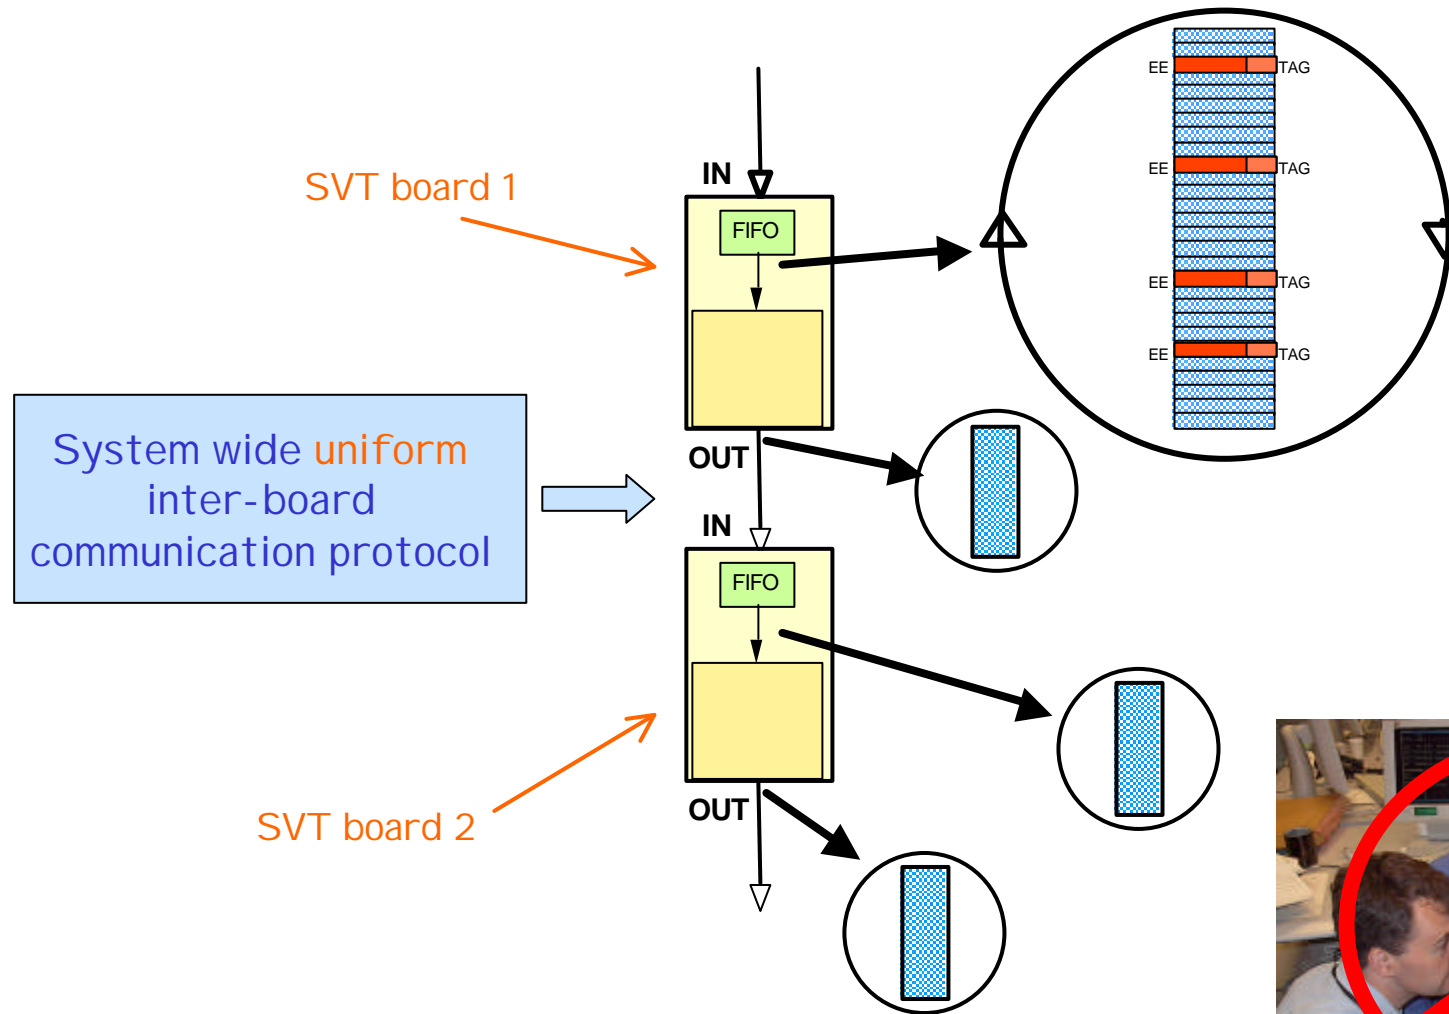

But the flexibility to adapt to the unforeseen was a big plus during commissioning

# Circular buffers monitor every data link: like a built-in logic analyzer

# On-crate monitoring of circular buffers

Sample hits, roads,  
tracks at high rate

Check boards against  
emulation software

Fit for beam position ...

# Online beamline fit / correction

$$\langle d \rangle = Y_{\text{beam}} \cos \phi - X_{\text{beam}} \sin \phi$$

# SVT board-on-a-chip

Input + output + one  
Altera APEX FPGA

- Modern FPGAs have impressive capabilities

Swiss army knife:

- Subtract beam offset
- Filter duplicate ("ghost") tracks
- Read diagnostic data into DAQ
- Measure timing

# Why SVT succeeded

- Performance:
  - Parallel/pipelined architecture
  - Custom VLSI pattern recognition
  - Linear track fit in fast FPGAs
- Reliability:
  - Easy to sink/source test data (many boards can self-test)
  - Modular design; universal, well-tested data link & fan-in/out
  - Extensive on-crate monitoring during beam running
  - Detailed CAD simulation before prototyping
    - ◆ See poster by Mircea Bogdan
- Flexibility:
  - System can operate with some (or all) inputs disabled
  - Building-block design: can add/replace processing steps
  - Modern FPGAs permit unforeseen algorithm changes
- Key: design system for easy testing/commissioning
