9

- 1895 Prof. Wilhelm Conrad Roentgen discovers X-rays
- Phosphor screens introduced early 20th century
- In the '70 years routine use of fluoroscopy with image intensifiers coupled to TV cameras
- In the '80 years 'the radiography becomes digital (imaging plates, CCDs, flat-panels, semiconductor detectors both amorphous and crystalline) M. Hoheisel, NIM A563 (2006) 215–224

## X-ray image versus CT scan

A conventional X-ray image is basically a **shadow**: you shine a “light” on one side of the body, and a piece of film on the other side registers the silhouette of the bones (to be more precise, **organs and tissues of different densities show up differently on the radiographic film**).

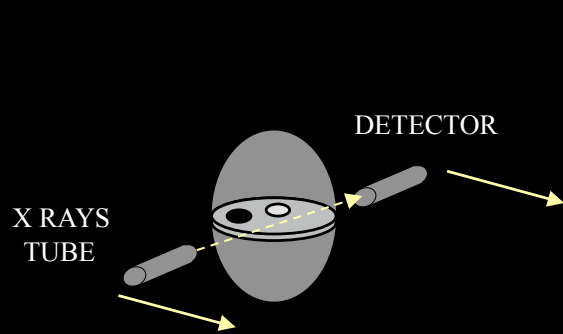

**Shadows give an incomplete picture of an object's shape.**

Look at the wall, not at the person. If there's a lamp in front of the person, you see the silhouette holding the banana, but not the pineapple as the shadow of the torso blocks the pineapple. If the lamp is to the left, you see the outline of the pineapple, but not the banana.

# X RAYS COMPUTERIZED TOMOGRAPHY (CT)

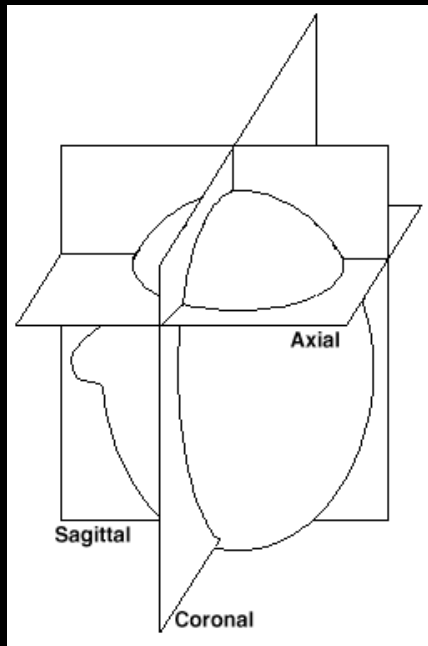

**A - LINEAR SAMPLING**

**B - ANGULAR SAMPLING**

**C - RECONSTRUCTION**

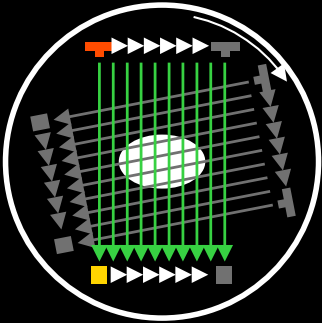

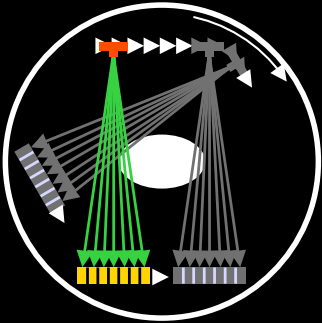

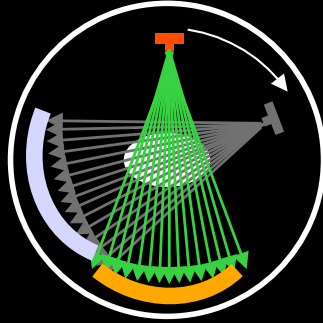

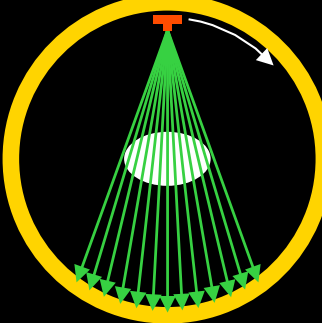

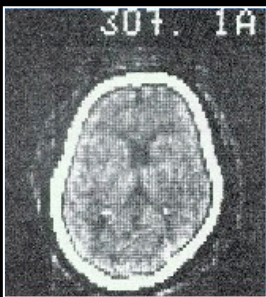

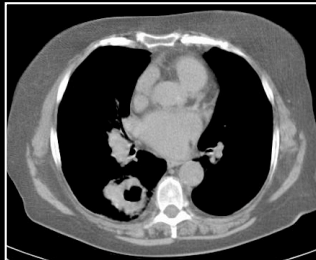

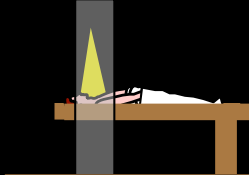

This is the basic idea of computer aided tomography. In a CAT scan machine, the X-ray beam moves all around the patient, scanning from hundreds of different angles. The computer takes all this information and puts together a **3-D image** of the body.

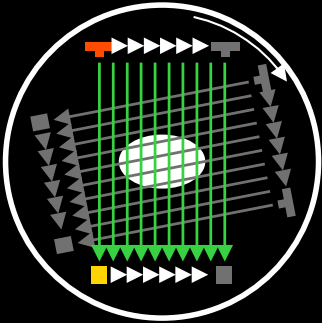

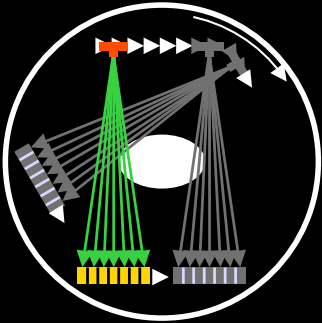

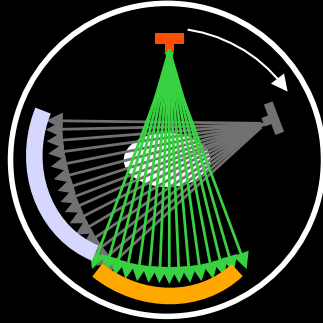

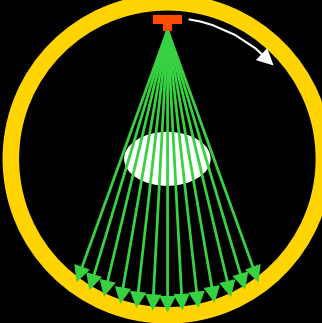

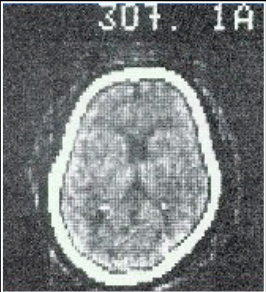

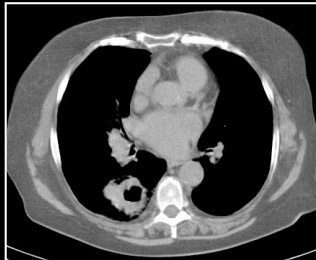

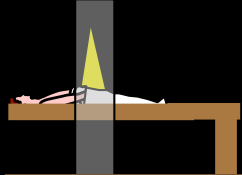

**X RAYS  
COMPUTERIZED TOMOGRAPHY**

# The Block Detector

1984-1985

**Burnham, Brownell** and colleagues at MGH developed a technique where scintillators were placed on a circular lightguide with photomultipliers placed on the opposite side of the lightguide. **Charlie Burnham** demonstrated that by taking the ratio of two adjacent photomultiplier signals, the scintillator that detected the gamma ray could be identified.

The block detector

**Mike Casey** and **Ronald Nutt**, from CTI, introduce the "Block" detector that was conceived as a means to simplify the Burnham detector and to make it easier to manufacture. Almost all dedicated tomographs built since 1985 have used some forms of the Block detector. This invention has made possible high-resolution PET tomographs at a much-reduced cost.

# Principle of Operation

27

In a block detector, a 2D array of crystals are attached to 4 PMTs. Usually the array will be cut from a single crystal and the cuts filled with light-reflecting material. When a photon is incident on one of the crystals, the resultant light is shared by all 4 PMTs. Information on the position of the detecting crystal may be obtained from the PMT outputs by calculating the following ratios and comparing them to pre-set values:

$$R_x = \frac{A + B}{A + B + C + D}$$

$$R_y = \frac{A + C}{A + B + C + D}$$

where  $A$ ,  $B$ ,  $C$  and  $D$  are the fractional amounts of light detected by each PMT

# From the block detector to PSPMT's

28

*“Block detector”*

- Large “b”

Small crystals can be used  
(down to d = 1mm)

Used in the  
YAP-(S)PET  
(Univ of Ferrara  
Italy, 1993)

Flood field irradiation (511 keV)  
of a matrix of scintillator YAP:Ce,  
read by a Hamamatsu R2486  
(resistive readout)

# Still PMTs?

29

Since more than 80 years, the PMT is the photodetector of choice to convert scintillation photons into electrical signals in most of the applications related to the radiation detection. This is due to its high gain, low noise and fast response

Research is now moving to solid state photodetectors that show the following advantages with respect to PMTs:

- Compactness
- High quantum efficiency (to provide an energy resolution comparable to PMTs)
- Insensitivity to magnetic fields( PET/MRI )

Avalanche Photodiodes (APDs)

Silicon  
Photomultipliers(SiPMs)  
o Geiger-mode APD

# Coding problem: “Individual coupling” with APD’s or light sharing with PSPMT’s

30

## APD

- + High spatial resolution ( $b=0$ )
- + No Pile-up
- + No scattering in the crystals
- Expensive
- Many channels
- Difficult tuning

The detector module is composed by a matrix of  $8 \times 4$  LSO crystals readout by a Hamamatsu S8550 (Pichler B., IEEE TNS 45 (1998) 1298-1302)

## 2<sup>nd</sup> generation PSPMT

Hamamatsu

PS-PMTR8520-C12

- Active area 22 mm  $\times$  22mm
- 6 x + 6 y anodes

- + Few channels to readout (resistive chain)
- + High gain and stability
- Non negligible coding error
- Pile-up increases with area
- 

# PET scintillators

Material	Density [g/cm <sup>3</sup> ]	Atomic numbers	Light yield [%NaI(Tl)]	Decay time [ns]	Peak wavelength [nm]	Time resolution [ns]	Index of refraction	Comments
NaI(Tl)	3.76	11,53	100	230	410	1.5	1.85	Hygroscopic Low density
BGO	7.13	83,32,8	15	300	480	7	2.15	Low light yield Slow
LSO	7.4	71,32,8	75	40	480	1.4	1.82	Intr. background 400 cps/cm <sup>3</sup>

YAP:Ce	5.37	39,13,8	55	27	370	1.1	1.95	Medium Z

Detectors are usually scintillators:  
the most often used is BGO (Bismuth germanate, Bi<sub>4</sub>Ge<sub>3</sub>O<sub>12</sub>) and more recently LSO (Lutetium Oxi-orto Silicate (LuSiO)).

# FUTURE DEVELOPMENTS IN PET

CURRENT DETECTORS: BGO, GSO, LSO

SANDWICH OF  
DETECTORS

NEW DETECTORS with:

- SMALLER SIZE (2-3 mm)
- GOOD ENERGY RESOLUTION
- DEPTH OF INTERACTION INFORMATION

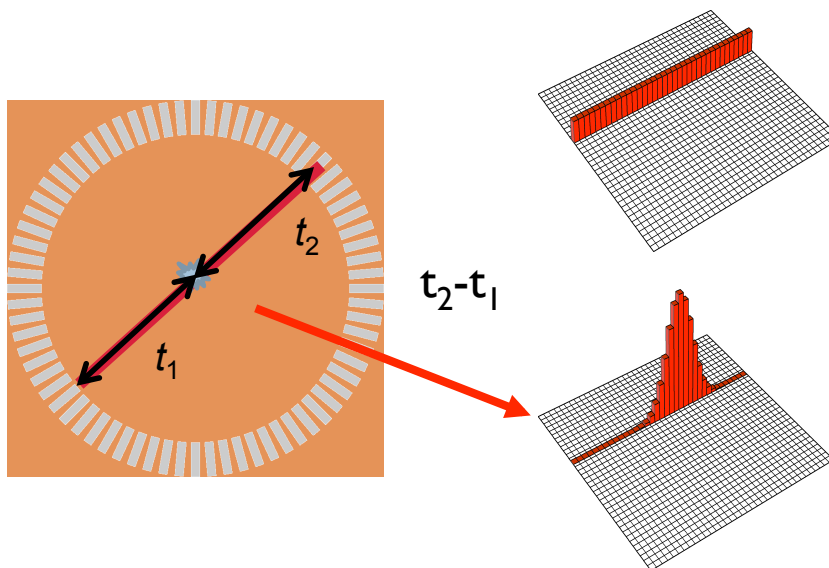

FASTER DETECTORS for

- HIGH COUNT RATE CAPABILITY
- TIME OF FLIGHT INFORMATION

# TOF systems: principle of operation

33

- ❑ TOF-PET systems exploit the time difference between the two emitted photons to better locate the annihilation position.
- ❑ The limit in the annihilation point location is mainly due to the error in the time difference measurement, namely the time resolution  $\Delta t$  of the coincidence system
- ❑ Time resolution is used by the reconstruction algorithm to locate the annihilation point  $\Delta x$  ( $\Delta x = c \Delta t / 2$ )

## PET traditional

The probability for the event to be located along the LOR is uniform

## PET Time-of-Flight

The most likelihood position is in the center of the error distribution

# Time Of Flight (TOF) systems

a “renaissance”

34

- 1) Development of new scintillators that combine fast decay time with high light yield and stopping power
- 2) Improvement of the performance and reliability of the PMTs and electronics
- 3) Progress in the image reconstruction algorithms

...made the coming back of time of flight systems possible, though already proposed in the '80s

*Gemini TF (Philips)*

*Biograph mCT (Siemens)*

PET studies of glucose metabolism to map human brain's response in performing different tasks. Subjects looking at a visual scene activated visual cortex (arrow), listening to a mystery story with language and music activated left and right auditory cortices (arrows), counting backwards from 100 by sevens activated frontal cortex (arrows), recalling previously learned objects activated hippocampus bilaterally (arrows), and touching thumb to fingers of right hand activated left motor cortex and supplementary motor system (arrows). Images are cross-sections with front of brain at top. Highest metabolic rates are in red, with lower values from yellow to blue.

**Volume 36, Supplement 1 / March, 2009**  
Multi-modality imaging: PET/MR

“PET/MR is a medical evolution based on a technical revolution”

“We believe that both PET/CT and PET/MR are here to stay, because both platforms incorporate the diagnostic power of PET.

In fact, with PET/CT being a “dual-modality imaging” platform by virtue of combining functional (PET) and anatomical (CT) imaging, PET/MR offers true “multimodality imaging” by virtue of combining function (PET) and anatomy and function (both MR). This will open, without a doubt, new avenues in non-invasive imaging as part of clinical patient management and clinical research”.

(T. Beyer and B. Pichler)

# Nuclear Magnetic Resonance

## THE BASIS OF NMR

The case of the spin half nucleus

A spinning nucleus has more energy when its magnetic field opposes the applied field

Nuclei are charged and many have spin which makes them magnetic

NO FIELD

Energy gap in field corresponds to radio frequency

EXCITATION

RELAXATION

# Equipment

Magnet

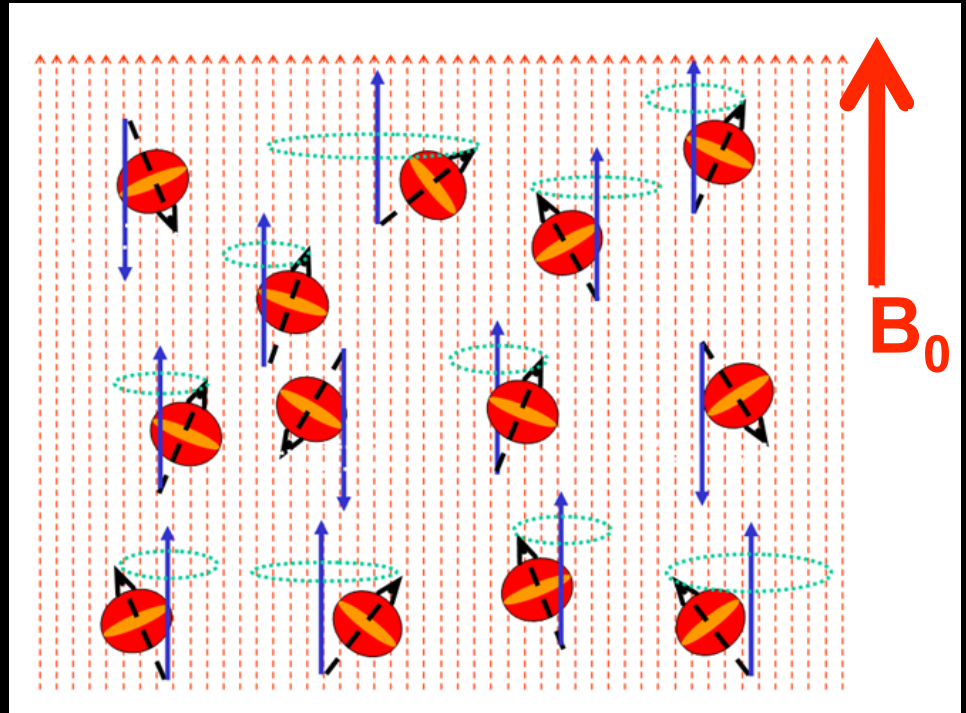

Gradient Coil

RF Coil

# Schematic illustration of motion in a magnetic field $B_0$ of protons

Larmor Frequency  $\omega = \gamma B_0$

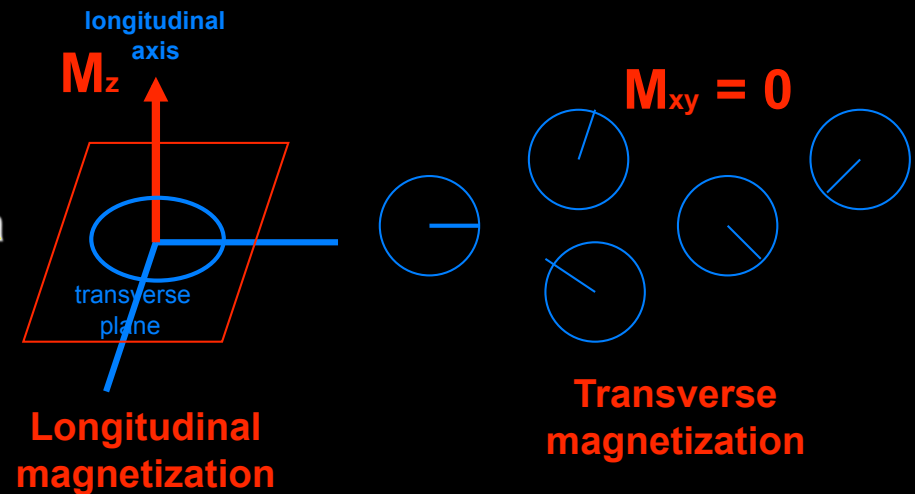

For hydrogen:

$\gamma = 42.58 \text{ MHz/Tesla} = 42.58 \times 10^6 \text{ Hz/Tesla}$

at 3 Tesla:

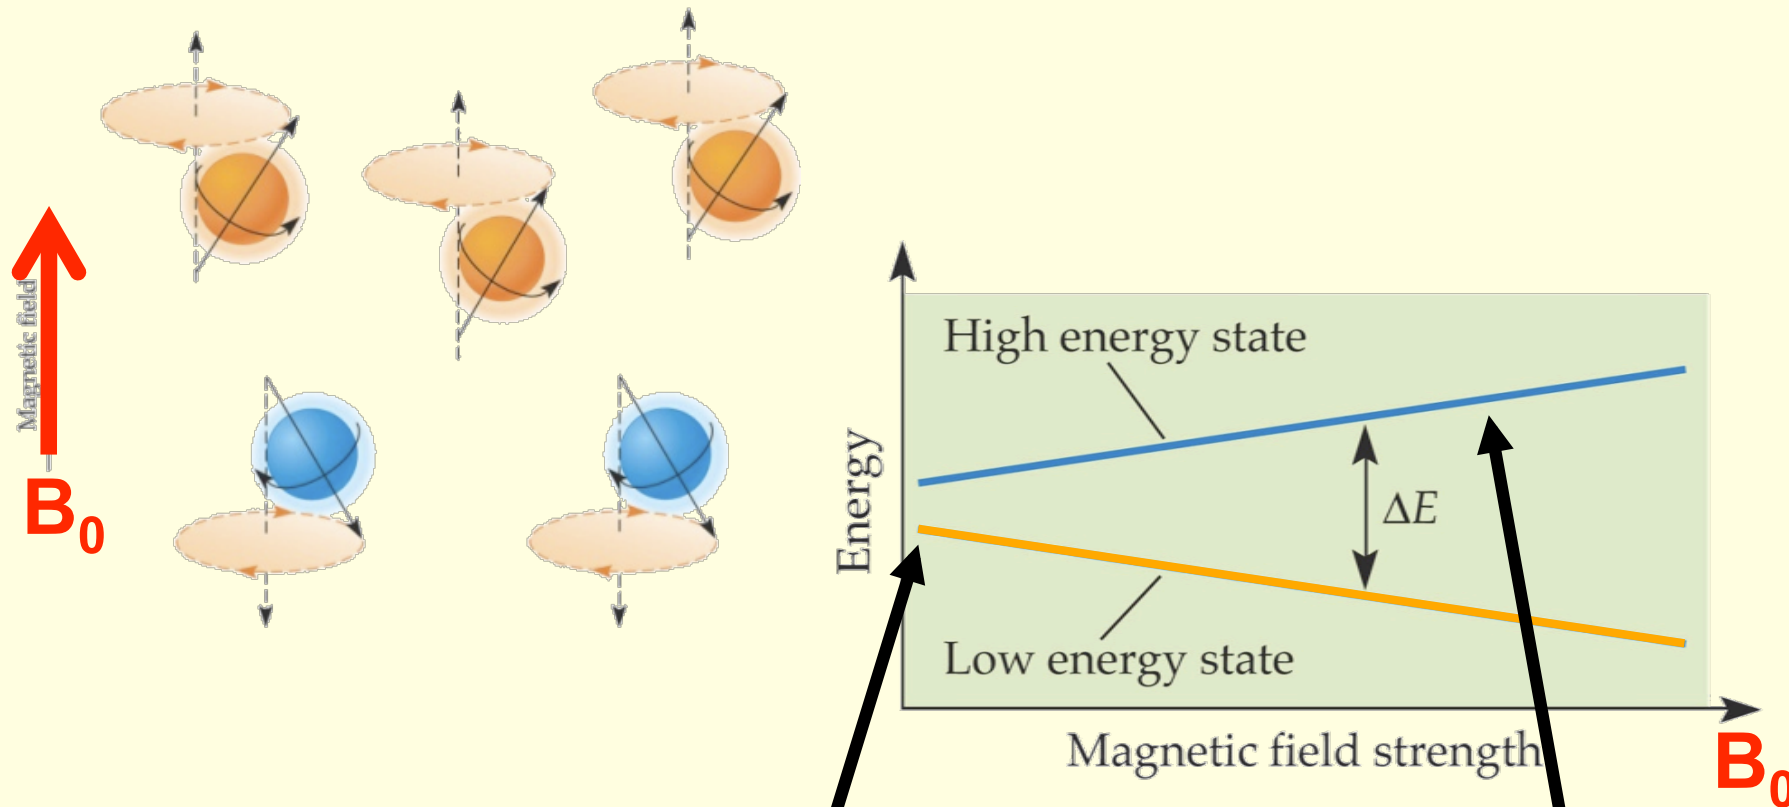

$\omega = (42.58 \text{ MHz / Tesla})(3 \text{ Tesla})$

$\omega = 127.74 \text{ MHz}$

# Energy states: Magnetic field effects

When the magnetic field is weak, little energy is required for a proton to change between high and low states ( $\Delta E$  is small).

But, when the magnetic field is strong, much more energy is required ( $\Delta E$  is large).

Thus, protons in the lower-energy state tend to stay in that state

# Energy states: Temperature effects

Protons move back and forth between states because of thermal energy.

The Boltzman equation describes the population ratio of the two energy states:

$$N^-/N^+ = e^{-E/kT}$$

Low-energy protons at room temperature in Earth's B:

~50.000000001%

High-energy protons at room temperature in Earth's B:

~49.999999999%

FUNCTIONAL MAGNETIC RESONANCE IMAGING, Figure 3.5 © 2004 Elsevier Associates, Inc.

- ◆ Larger  $B_0$  produces larger net magnetization  $M$ , lined up with  $B_0$
- ◆ Thermal motions try to randomize alignment of proton magnets
- ◆ At room temperature, the population ratio is roughly 100,000 to 100,006 per Tesla of  $B_0$

# Excite Radio Frequency (RF) field

- apply RF represented here with a magnetic field  $B_1$  (perpendicular to  $B_0$ ) oscillating at Larmor frequency
- Larmor frequencies in RF range;  $B_1$  is small:  $\sim 1/10,000$  T
- tips  $M$  to transverse plane – spirals down

(A)

Rotating frame

(B)

Laboratory frame

The RF energy is represented here with  $B_1$  as a second magnetic field superimposed to  $B_0$ .

# Relaxation:

- Once we stop applying energy, M will go back to being aligned with static field  $B_0$
- This process is called relaxation
- The part of M perpendicular to  $B_0$  shrinks [ $M_{xy}$ ]
  - This part of M is called *transverse magnetization*
  - It provides the detectable RF signal
- Part of M parallel to  $B_0$  grows back [ $M_z$ ]
  - This part of M is called *longitudinal magnetization*

# Tipping the net magnetization provides measurable MR signal!

Excitation tips the net magnetization ( $M$ ) down into the transverse plane, where it can generate current in detector coils (i.e., via induction).

The amount of current oscillates at the (Larmor) frequency of the net magnetization.

# Relaxation Times and Rates

- Net magnetization changes in an exponential fashion
  - Constant rate (R) for a given tissue type in a given magnetic field
  - $R = 1/T$ , leading to equations like  $e^{-Rt}$
- $T_1$  (recovery): Relaxation of  $M$  back to alignment with  $B_0$ 
  - Usually 500-1000 ms in the brain (lengthens with bigger  $B_0$ )
- $T_2$  (decay): Loss of transverse magnetization over a microscopic region ( $\approx$  5-10 micron size)
  - Usually 50-100 ms in the brain (shortens with bigger  $B_0$ )
- $T_2^*$ : Overall decay of the observable RF signal over a macroscopic region (millimeter size)
  - Usually about half of  $T_2$  in the brain (i.e., faster relaxation)

# $T_1$ and $T_2$ values at 1.5T

<u>Tissue</u>	<u><math>T_1</math> (s)</u>	<u><math>T_2</math> (ms)</u>

# MAGNETIC RESONANCE IMAGING

EXCITATION

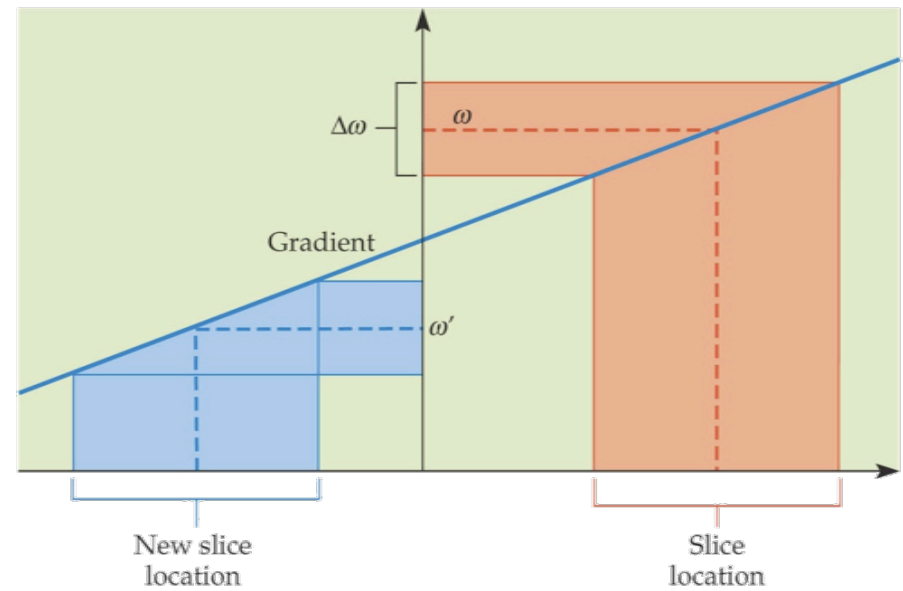

RELAXATION

# Apply a z-gradient field $G_z$ for slice selection

Gradients change the Strength, not Direction of the Magnetic Field  $B_0$

# Spatial encoding within the slice

The selected slice is then subdivided in a matrix of voxels along the x,y coordinates applying the gradient fields  $G_x$  and  $G_y$  with a procedure called Phase and Frequency encoding.

# Phase Encoding

When the gradient field  $G_y$  (that vary linearly along the y-axis) is applied, all the spins of the voxels of the matrix line at a given y-coordinate start to process at the same Larmor frequency with the same phase, while all the other voxel lines at different y-coordinate process with different Larmor frequencies and therefore, in a given amount of time, accumulate a certain amount of phase offset.

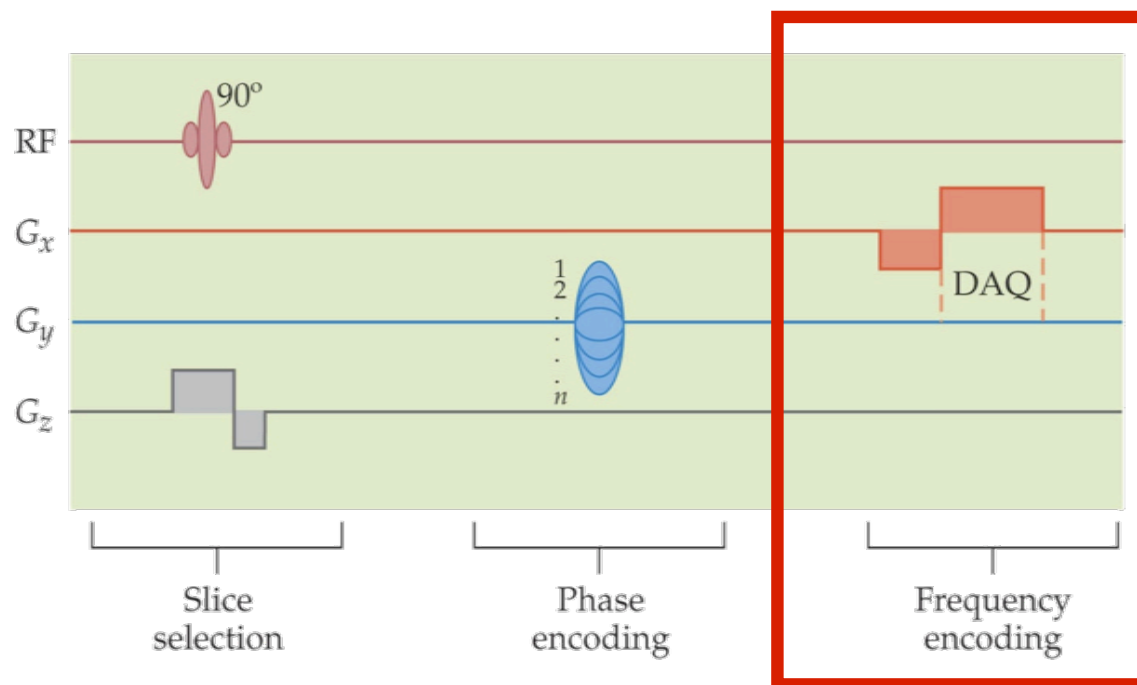

When the phase encoding gradient  $G_y$  is turned off all the spins of the voxels of all the lines return to process at the same frequency but now with different phases, determined by the duration and the intensity of  $G_y$  (Phase Encoding).

# Frequency Encoding

When the phase encoding process have been completed, the gradient field  $G_x$  (that vary linearly along the x-axis) is turned on and therefore the spins of the voxels of the matrix columns at different y-coordinate are forced to process at different Larmor frequencies (Frequency Encoding).

At this point each individual voxel is going to have a different combination of phase and frequency and the Data Acquisition (DAQ) of the raw MR signals can be performed.

The complete image of the selected slice can then be obtained performing a 2-D inverse Fourier transform of the raw signal. This is possible because the raw MR signal acquired contains, through the phase and frequency encoding, the information from each individual voxel

# T1-weighted and T2-weighted sequences

# Technology for MR/PET

73

- (1) Scintillating crystals plus photomultiplier tubes (PMT)
- (2) Scintillating crystals plus solid state light detectors

# Technology for MR/PET (1)

74

## □ PMT Approach

- Well understood, stable electronics, high gain ( $10^6$ )
- However, Position sensitive PMT (PSPMT) operate in 1mT
- Combination of distance (light guide) and iron shield (1-2mm of soft iron can further reduce 30mT  $\rightarrow$  1mT) to operate in 1mT

# Technology for MR/PET (1)

75

# Technology for MR/PET (1)

76

- 1 mT has minimal effect on PSPMT performance
- Long light guides reduce energy resolution from 17 -> 27%, but this shouldn't have too big an impact upon performance
- Can perform simultaneous and isocentric MR/PET measurements
- However, small axial FOV

# Technology for MR/PET (2)

77

- Solid state devices
  - ▣ Avalanche Photodiodes (gain  $\sim 150$ )
  - ▣ Silicon Photomultiplier (gain  $\sim 10^6$ )
  - ▣ Less well established as PET detectors
- Can operate in high static field  $> 7T$
- Need to shield devices from both gradients and RF

## SOLID STATE PHOTODETECTOR → SiPM: Multicell Avalanche Photodiode working in limited Geiger mode

- The photon is absorbed and generates an electron/hole pair
- The electron/hole diffuses or drifts to the high-electric field multiplication region
- The drifted charge undergoes impact ionization and causes an avalanche breakdown.
- Resistor in series to quench the avalanche (limited Geiger mode).

As produced at FBK-irst, Trento, Italy →

- 2D array of microcells: structures in a common bulk.
- $V_{bias} > V_{breakdown}$ : high field in multiplication region
- Microcells work in Geiger mode: the signal is independent of the particle energy
- The SiPM output is the sum of the signals produced in all microcells fired.

→ High gain → Low noise → Good proportionality if  $N_{photons} \ll N_{cells}$

# Characterization

81

□ Collaboration with FBK-irst (Trento, been developing SiPMs since 2005:

- First detectors - Single SiPMs (2006)
- First matrices 2x2 (2007)
- First matrices 4x4 (2008)
- First matrices 8x8 (2009)

□ Breakdown voltage  $V_B \sim 30V$ , very

□ Gain:  $\sim 10^6$

- Linear for a few volts over  $V_{BD}$ .
- Related to the recharge of the diode capacitance  $C_D$  the avalanche quenching.  $G=(V_{BIAS}-V_B) \times C_D/q$

□ Dark rate:

- 1-3 MHz at 1-2 photoelectron (p.e.) level,  $\sim$ kHz at 3-4  $\mu$
- Not a concern for PET applications.

# Results: New detectors (May 2007)

82

**Different geometry, size, microcell size and GF.**

$40 \times 40 \mu\text{m}^2 \Rightarrow \text{GF } 44\%$   
 $50 \times 50 \mu\text{m}^2 \Rightarrow \text{GF } 50\%$   
 $100 \times 100 \mu\text{m}^2 \Rightarrow \text{GF } 76\%$

□ Matrices 16 elements (4x4)

**IV CURVES OF 9 MATRICES.**

**VERY UNIFORM BREAKDOWN POINT**

[C.Piemonte et al, *Il Nuovo Cimento C*, 2007,30(5),473-482]

# Silicon Drift Detector

- ❑ low detector capacitance  $\Rightarrow$  low electronics noise
- ❑ JFET integrated on the detector chip
- ❑ homogeneous entrance window, with ARC for scintillation detection
- ❑ low leakage current necessary ( $\sim 300\text{pA/cm}^2$  @RT available at MPI-HLL)
- ❑ availability of monolithic arrays of SDDs

## Summary of accelerators running in the world

CATEGORY OF ACCELERATORS	NUMBER IN USE (*)
High Energy acc. (E >1GeV)	~120
Synchrotron radiation sources	>100
<u>Medical radioisotope production</u>	<u>~200</u>
<u>Radiotherapy accelerators</u>	<u>&gt; 7500</u>
<u>Research acc. included biomedical research</u>	<u>~1000</u>
Acc. for industrial processing and research	~1500
Ion implanters, surface modification	>7000
<b>TOTAL</b>	<b><u>&gt; 17500</u></b>

9000

(\*) W. Maciszewski and W. Scharf: Int. J. of Radiation Oncology, 2004

## ***High-current cyclotrons used in medicine***

### **Baby Cyclotrons (below 18 MeV)**

*In-house facility*

Mainly used for production of short-lived positron emitters  
like  $^{18}\text{F}$ ,  $^{11}\text{C}$ ,  $^{13}\text{N}$ ,  $^{15}\text{O}$ .

### **Medium Energy Cyclotrons (below 40 MeV)**

*Centralised facility*

Majority of the cyclotron produced isotopes are produced  
using such machine viz,  $^{123}\text{I}$ ,  $^{201}\text{Tl}$ ,  $^{67}\text{Ga}$ ,  $^{68}\text{Ga}$ ,  $^{103}\text{Pd}$  etc.

### **High Energy Cyclotrons (above 40 MeV)**

*Centralised facilities and research institutions*

Used for production of few radioisotope requiring high  
energy for production viz,  $^{67}\text{Cu}$ ,  $^{82}\text{Sr}$ ,  $^{211}\text{At}$ .....

## *Baby cyclotrons*

General Electric

16.5 MeV

Ion Beam Applications

18 MeV

Accelerated particles:  $H^-$

## Medium energy cyclotrons

30 MeV protons, 500-1000  $\mu\text{A}$

IBA  
Belgium

ACS  
Canada

## High-energy cyclotrons

IBA's ARRONAX in Nantes

4 Particles:  $H^-$  /  $D^-$  /  $He^{2+}$  /  $HH^+$

Variable energy: 15 MeV  $\rightarrow$  70 MeV

Performances:

- 750  $\mu$ A  $H^-$
- 35  $\mu$ A  $He^{2+}$

# **ACCELERATORS IN CANCER THERAPY**

## **'Conventional' radiotherapy: linear accelerators dominate**

**In the world radiation oncologists use 15 000 electron linacs  
40% of all the existing accelerators**

# Medical accelerators: electron linac

Varian Clinac 1800 installed in the S. Anna Hospital in Como (Italy)

# X rays have a poor energy deposition

IMRT (Intensity Modulated Radiation Therapy) with 9 crossed beams

Tumour between the eyes

# *“Hadrontherapy” uses n, p and C-ion beams*

# Ionization: the Bethe-Bloch formula

$$\left\langle \frac{dE}{dx} \right\rangle = -4\pi N_A r_e^2 m_e c^2 z^2 \frac{Z}{A} \frac{1}{\beta^2} \left[ \frac{1}{2} \ln \frac{2m_e c^2 \gamma^2 \beta^2}{I^2} T^{\max} - \beta^2 - \frac{\delta}{2} \right]$$

$$T_{\max} \approx 2m_e c^2 \beta^2 \gamma^2 \quad \left[ -\frac{dE}{dx} \approx K q^2 \frac{Z}{A \beta^2} \left[ \ln \frac{2m_e c^2 \beta^2 \gamma^2}{I^2} - \beta^2 \right] \right]$$

Characterized by:

- a fall off at low energy  $\sim 1/\beta^2$
- a relativistic rise  $\sim \ln \beta\gamma$
- a minimum at  $\beta\gamma \approx 3$
- depends only on  $\beta\gamma$  not on  $m$

High energy charged particles lose energy **slowly** in material due to ionization leaving tracks as they pass ( For  $Z \approx 0.5A$  at  $\beta\gamma \approx 3$   $1/\rho dE/dx \approx 1.4 \text{ MeV cm}^2/\text{g}$  )

→ many kinds of tracking detectors can be done !

# Depth Dose Profile

# Charged hadrons have a much better energy deposition

200 MeV protons

4800 MeV carbon ions

which control radioresistant tumours

## ***Charged hadrons can deliver the dose in three dimensions***

**Longitudinal movement by varying the energy of the beam**

## ***Charged hadrons can deliver the dose in three dimensions***

**Lateral movement with a transverse magnetic field**

# Magnetic scanning with pencil beam

- Fully 3d conformal (fixed range modulation)
- Fully automated (no specific hardware needed)

## Protons are qualitatively different from X-rays

Carbon ions deposit in a cell 24 times more energy than a proton producing not reparable multiple close-by double strand breaks

Carbon ions can control radio-resistant tumours

## Trasferimento tecnologico

Particle physics software aids space and medicine

*"Geant4 is a showcase example of technology transfer from particle physics to other fields such as space and medical science [...]"*

CERN Courier, June 2002

# Software di Simulazione

E' stato sviluppato un sistema dosimetrico, basato su simulazione Montecarlo, con lo scopo di ricavare sia la **distribuzione di dose** in tre dimensioni, sia le relative curve di isodose nei tessuti.

## Geant 4<sup>(1)</sup>

software basato su un'architettura ed una programmazione orientata agli oggetti

processo di sviluppo rigoroso basato sul metodo iterativo incrementale

interfaccia astratta utilizzo versatile per l'utente

Contemporaneamente si rende necessario uno strumento per il confronto statistico (Goodness of Fit) delle curve/distribuzioni simulate con i dati sperimentali .

# Adroterapia

Fa uso di fasci di protoni che depositano dosi terapeutiche di radiazione vicino al tumore, utilizzando tecniche di precisione balistica.

Picco di Bragg

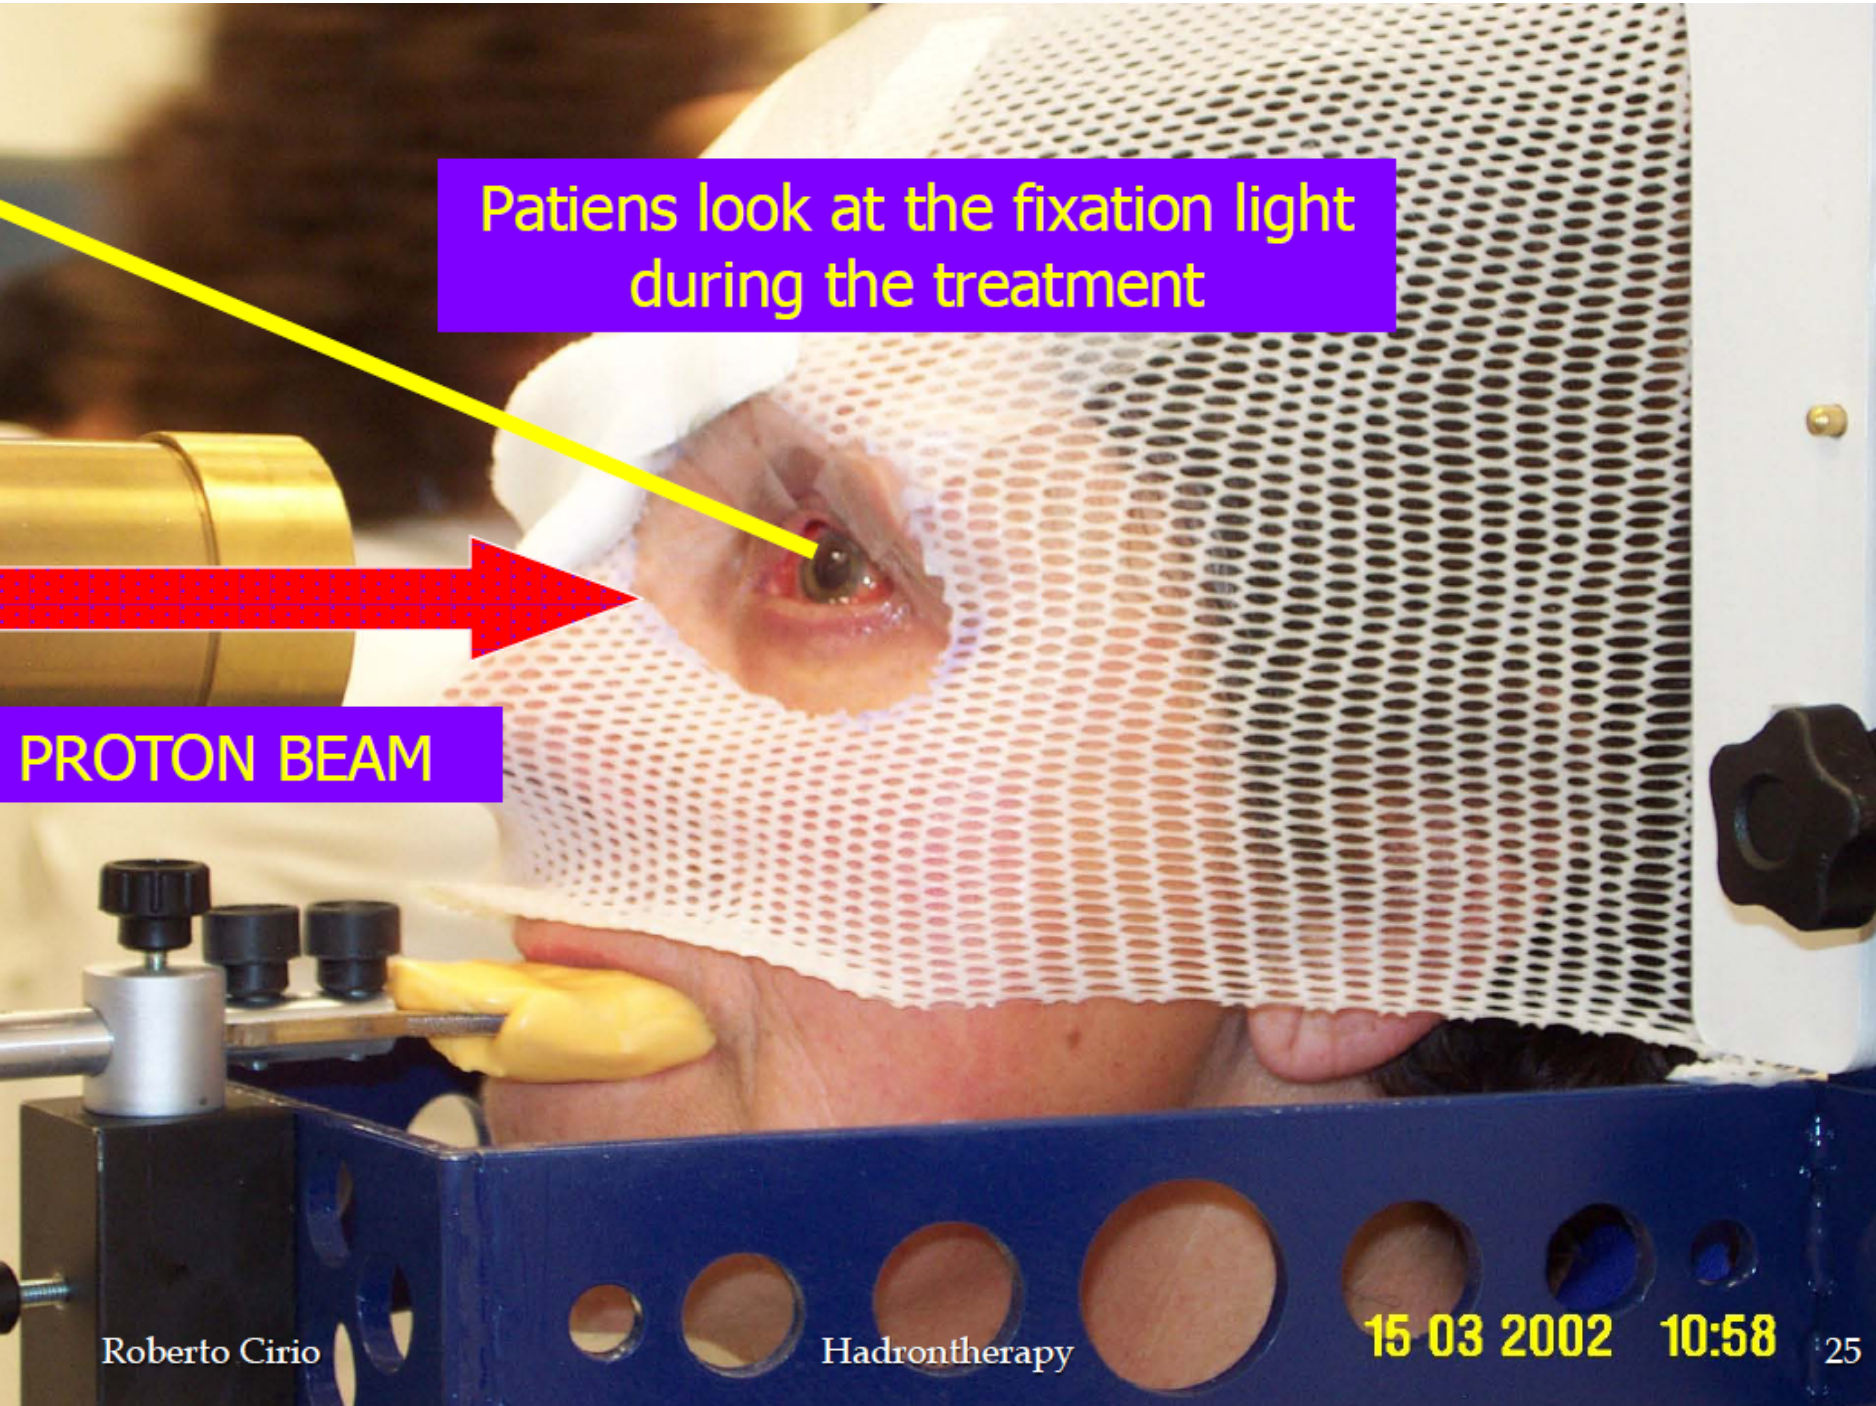

Geant4

Adroterapia  
con protoni  
Melanoma oculare

Patients look at the fixation light  
during the treatment

PROTON BEAM

# Protoni - picco di Bragg - Acqua

Protons - Bragg Peak

Dati sperimentali acquisiti presso ESPERIMENTO CATANA (INFN, LNS Catania)

Le simulazioni del picco di Bragg basate sul toolkit Geant4 (LowE) rappresentano uno strumento valido per la simulazione dei piani di trattamento negli studi di adroterapia applicati di melanoma oculare.

<http://www.lns.infn.it/catanaweb>

# Particelle e grandezze fisiche studiate

**Elettroni**

CSDA Range, Potere frenante, Coefficienti di trasmissione, Coefficienti di backscattering.

**Fotoni**

Coefficienti di assorbimento e di trasmissione, sezioni d'urto.

**Positroni**

Coefficienti di trasmissione e di backscattering

**Protoni**

CSDA Range, Potere frenante, picco di Bragg

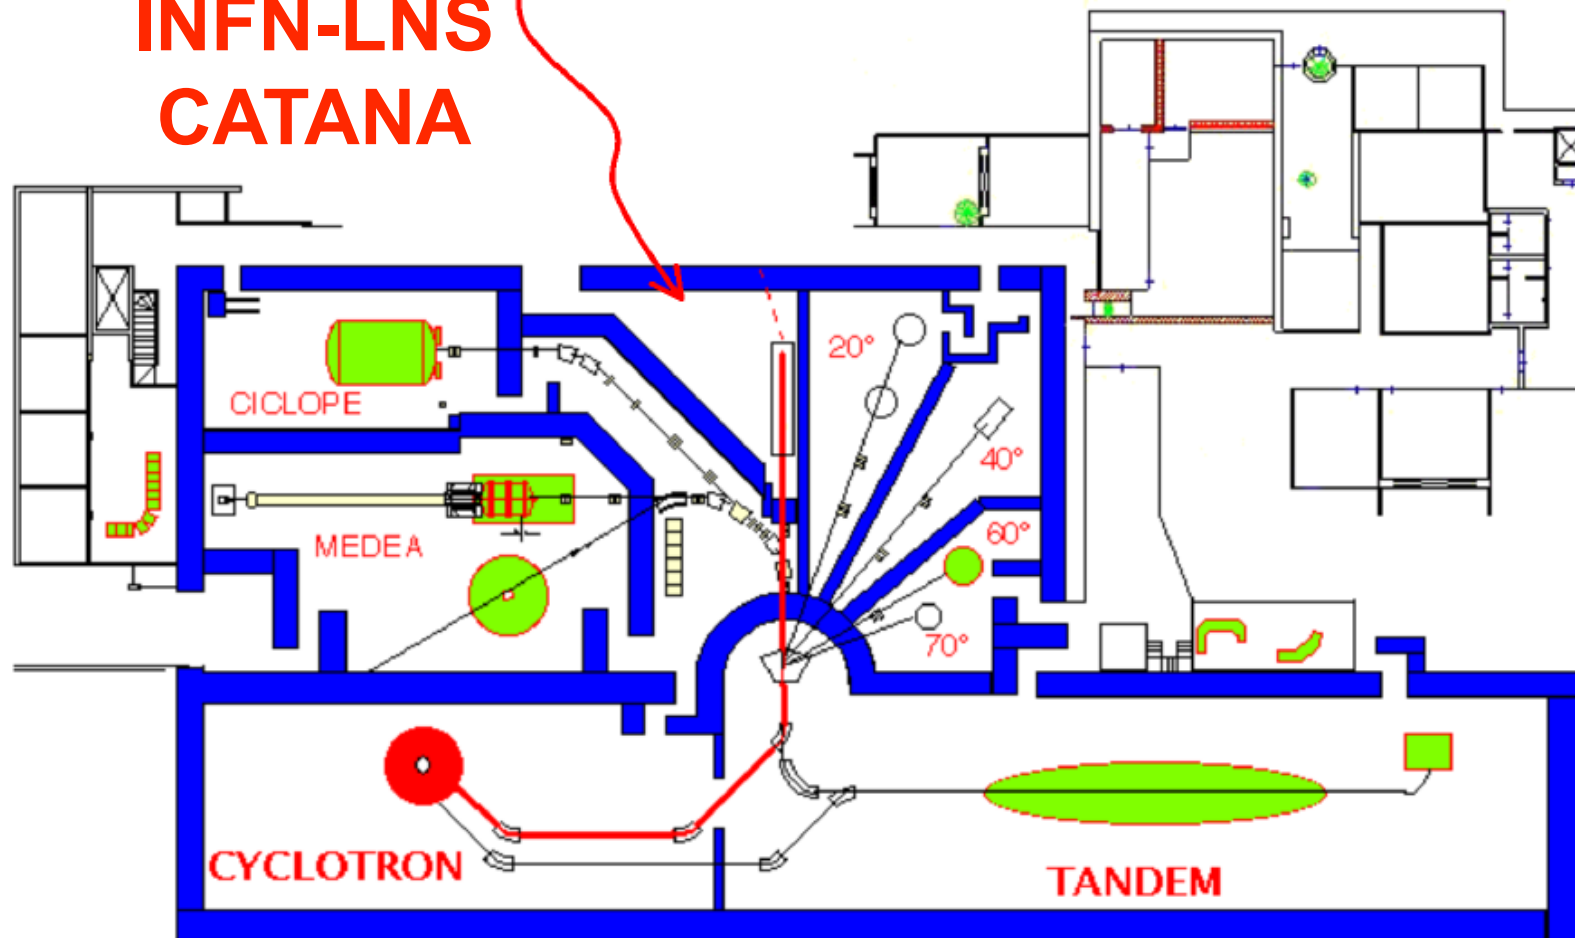

Le grandezze fisiche sono state simulate per TUTTI gli elementi della tavola periodica (circa 100)

## PRESENT TREATMENT ROOM

- 0 ° respect the switching magnet
- 80 meter after extraction
- 3 m proton beam line

## INFN-LNS CATANA

## Loma Linda Medical University Centre: first patient 1992

- First hospital-based proton-therapy centre

Built at  
Fermilab

## ***Hospital centres for deep protontherapy ( >500 pts/year)***

5 in USA, 4 in Japan, 2 in China, 1 in Switzerland, 1 in Germany,  
1 in Korea, 1 in Italy  
(running or financed)

**Five companies offer turn-key centres**

**Protontherapy: cyclotrons and synchrotrons...**

# HIMAC in Chiba is the pioner of carbon therapy (Prof H. Tsujii)

Yasuo Hirao

<sup>15</sup> Hirao, Y. et al, "Heavy Ion Synchrotron for Medical Use: HIMAC Project at NIRS Japan" Nucl. Phys. A538, 541c (1992)

5000 pts 1994-2009

## The Hyogo 'dual' Centre

End of 2008  
protons: 2000 patients  
carbon ions: 500 patients

**Mitsubishi: turn-key system**

# Japan: 4 proton Centres and 2 carbon ion centres

**WAKASA BAY PROJECT**  
 by Wakasa-Bay Energy Research Center  
 Fukui (2002)  
 protons ( $\leq 200$  MeV) synchrotron  
 (Hitachi)  
 1 h beam + 1 v beam + 1 gantry

**TSUKUBA CENTRE**  
 Ibaraki (2001)  
 protons ( $\leq 270$  MeV)  
 synchrotron (Hitachi)  
 2 gantries  
 2 beam for research

**HYOGO MED CENTRE**  
 Hyogo (2001)  
 protons ( $\leq 230$  MeV) - He and C ions ( $\leq 320$  MeV/u)  
 Mitsubishi synchrotron  
 2 p gantries + 2 fixed p beam + 2 ion rooms

**KASHIWA CENTER**  
 Chiba (1998)  
 protons ( $\leq 235$  MeV)  
 cyclotron (IBA – SHI)  
 2 Gantries + 1 hor. beam

**HEAVY ION MEDICAL ACCELERATOR**  
 HIMAC of NIRS (1995)  
 He and C ( $\leq 430$  MeV/u) 2 synchrotrons  
 2 h beams + 2 v beams

**2000 patients  
 with carbon ions**

**SHIZUOKA FACILITY**  
 Shizuoka (2002)  
 Proton synchrotron  
 2 gantries + 1 h beam

**50 patients  
 with carbon ions**

**Gerhard Kraft**

**J. Debus**

## ***Germany: the GSI pilot project***

**1998-2009**  
**500 patients treated**  
**with carbon ions**

# Patients of hadrontherapy

Protontherapy:  
60'000 patients  
Carbon ion therapy  
5 000 patients  
mainly at HIMAC

Cost about 20'000 Euro  
2-3 x X-rays  
If cost would be the  
same as for X-rays  
90% of the treatments  
would be with  
protons !

## Eye and Orbit

- Choroidal Melanoma
- Retinoblastoma
- Choroidal Metastases

Roboter

## *TERA programmes since 1992*

TERA has proposed and designed the 'dual' National Centre for carbon ions and protons

**1. CNAO is being built in Pavia**

TERA has introduced and developed a novel type of accelerator:  
the "cyclinac"

**2. "cyclinacs for protons and carbon ions"**

## ***CNAO = Centro Nazionale di Adroterapia***

**CNAO Foundation was created by the Italian Government in 2001  
to realize CNAO: 4 Hospitals in Milan, 1 Hospital in Pavia and TERA**

**Since 2003 INFN is Institutional Participant**

**In September 2003 TERA has completed and passed to CNAO  
the design of the high-tech part of CNAO and 25 people**

**President: E. Borloni**

**Med. Dir.: R. Orecchia**

**Tech. Dir: S. Rossi**

# First Clinical Positron Imaging Device

1952

This instrument followed the general concepts of the instrument build in 1950 but included many refinements. It produced both a coincidence scan as well as an unbalance scan. The unbalance of the two detectors was used to create an unbalance image using two symbols to record any unbalance in the single channel rates of the two detectors.

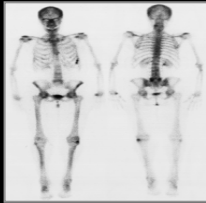

First clinical positron imaging device.

Dr. Brownell (left) and Dr. Aronow are shown with the scanner (1953).

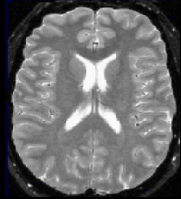

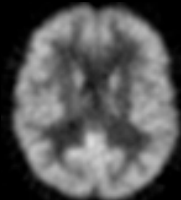

Coincidence and unbalance scans of patient with recurring brain tumor. Coincidence scan (a) of a patient showing recurrence of tumor under previous operation site, and unbalance scan (b) showing asymmetry to the left. (Reproduced from Brownell and Sweet 1953 ).
